02	Game Design	08	Training
03	State Representation	09	Results
04	Action Encoding	11	Human Trials
05	Rewards	10	Reference
06	Setting		

Introduction

Introduction

The Project

- We will formalize as a RL problem the two - player variant of Briscola, one of the most popular card games in Italy.
- The agent will be trained using the Deep Q Networks algorithm.
- The win rate and average reward will be used as a performance measure to compare the final results.

Introduction

Briscola Rules

Number of players

Between 2 or 6. They can either play individually or in teams.

We will only present the 2 players version.

Rules

Trick-taking game. A player leads by playing a card and the others take turns and try to beat it with a higher card in that suit or a card from the same suit of the "briscola"

Winner

Whoever wins each round leads the next one. To win the game a player, or a team, have to accumulate more points than the other players, or teams.

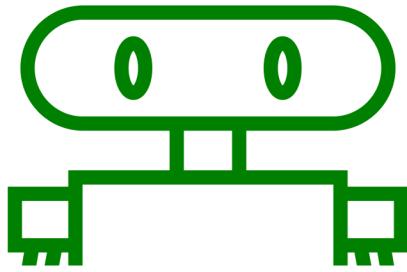

Introduction

Steps

Environment

The first necessary step was to clearly define the Reinforcement Learning environment

Agent

Then the chosen algorithm was implemented through the use of the agent

Evaluation

At last, the agent was trained and different tests were performed to evaluate its performance

RLCard

Overview

RLCard is a Python library for reinforcement learning in card games, providing a standardized environment and a collection of pre-implemented algorithms and agents.

Why did we use it?

We chose the RLCard framework because, by creating a new game environment compatible with the toolkit's specifications, we gained access to the extensive repository of pre-existing code, functions, and agents within RLCard.

Each game in the toolkit shared common base classes, each embodying a distinct abstract concept.

Game Design

Game Design

Player

- **Definition:** The active participant in the game
- **Player Class Role:**
 - Player **initialization**
 - Keeping track of personal information (**player_id/score**)

Game Design

Game

- **Definition:** A complete sequence from non-terminal to terminal states
- **Game Class Role:**
 - **Initialization** (players/deck)
 - **Evolution Management** (round progression, payoffs)

Game Design

Round

- **Definition:** A segment within the game sequence
- **Round Class Role:**
 - Execution of **single round**
 - Player **turn** management
 - **Score update at round end**

Game Design

Dealer

- **Definition:** Handles deck management
- **Dealer Class Role:**
 - **Initialization** (Italian card deck)
 - **Card shuffling**
 - **Briscola setting**
 - **Card dealing management**

Game Design

Judger

- **Definition:** Major decision-maker in a round or end of a game
- **Judger Class Role:**
 - Implementing scoring system
 - Determining Round Winner
 - Determining Game Winner

State Representation

State Representation

- **Definition:** Information observable by one player at a specific game time step
- **Toolkit Standard:** State represented as a dictionary with two values
 - Observations
 - Legal Actions list

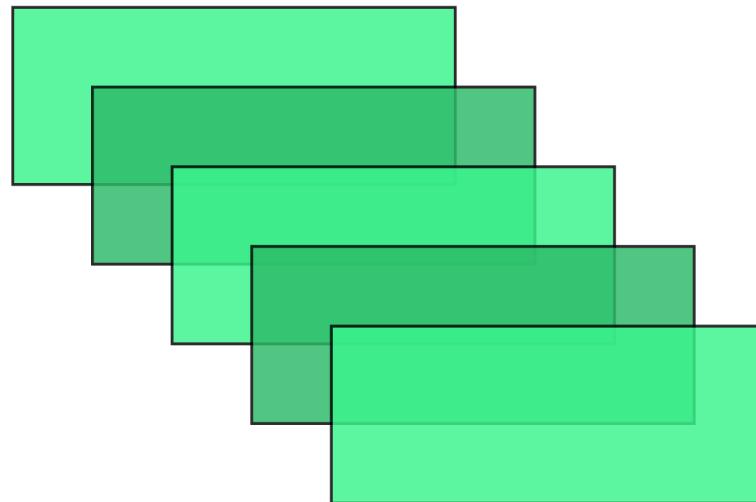

State Representation

Observation Encoding

Observations were encoded into a **Matrix of 5 Card Planes**, one-hot encoded in a 4 by 10 grid

- Player's current Hand
- Table Cards
- Briscola Card
- Face down pile in front of Player 0
- Face down pile in front of Player 1

$5 \times 4 \times 10$

Action Encoding

Action Encoding

- **Definition:** Conversion of specific game actions into action indices
- **Format:** Positive integers, from 0 to 39
- **Correspondence:** Each index represents a unique game action
- **Legal Actions:** Represented as a list of action indices. They are the only actions an agent can choose from and are comprised of the cards in the player's hand

Rewards

Rewards

Per Game

- Rewards are assigned when the game is over.
 - +1 for Winning
 - -1 for Losing
 - 0 for a Draw

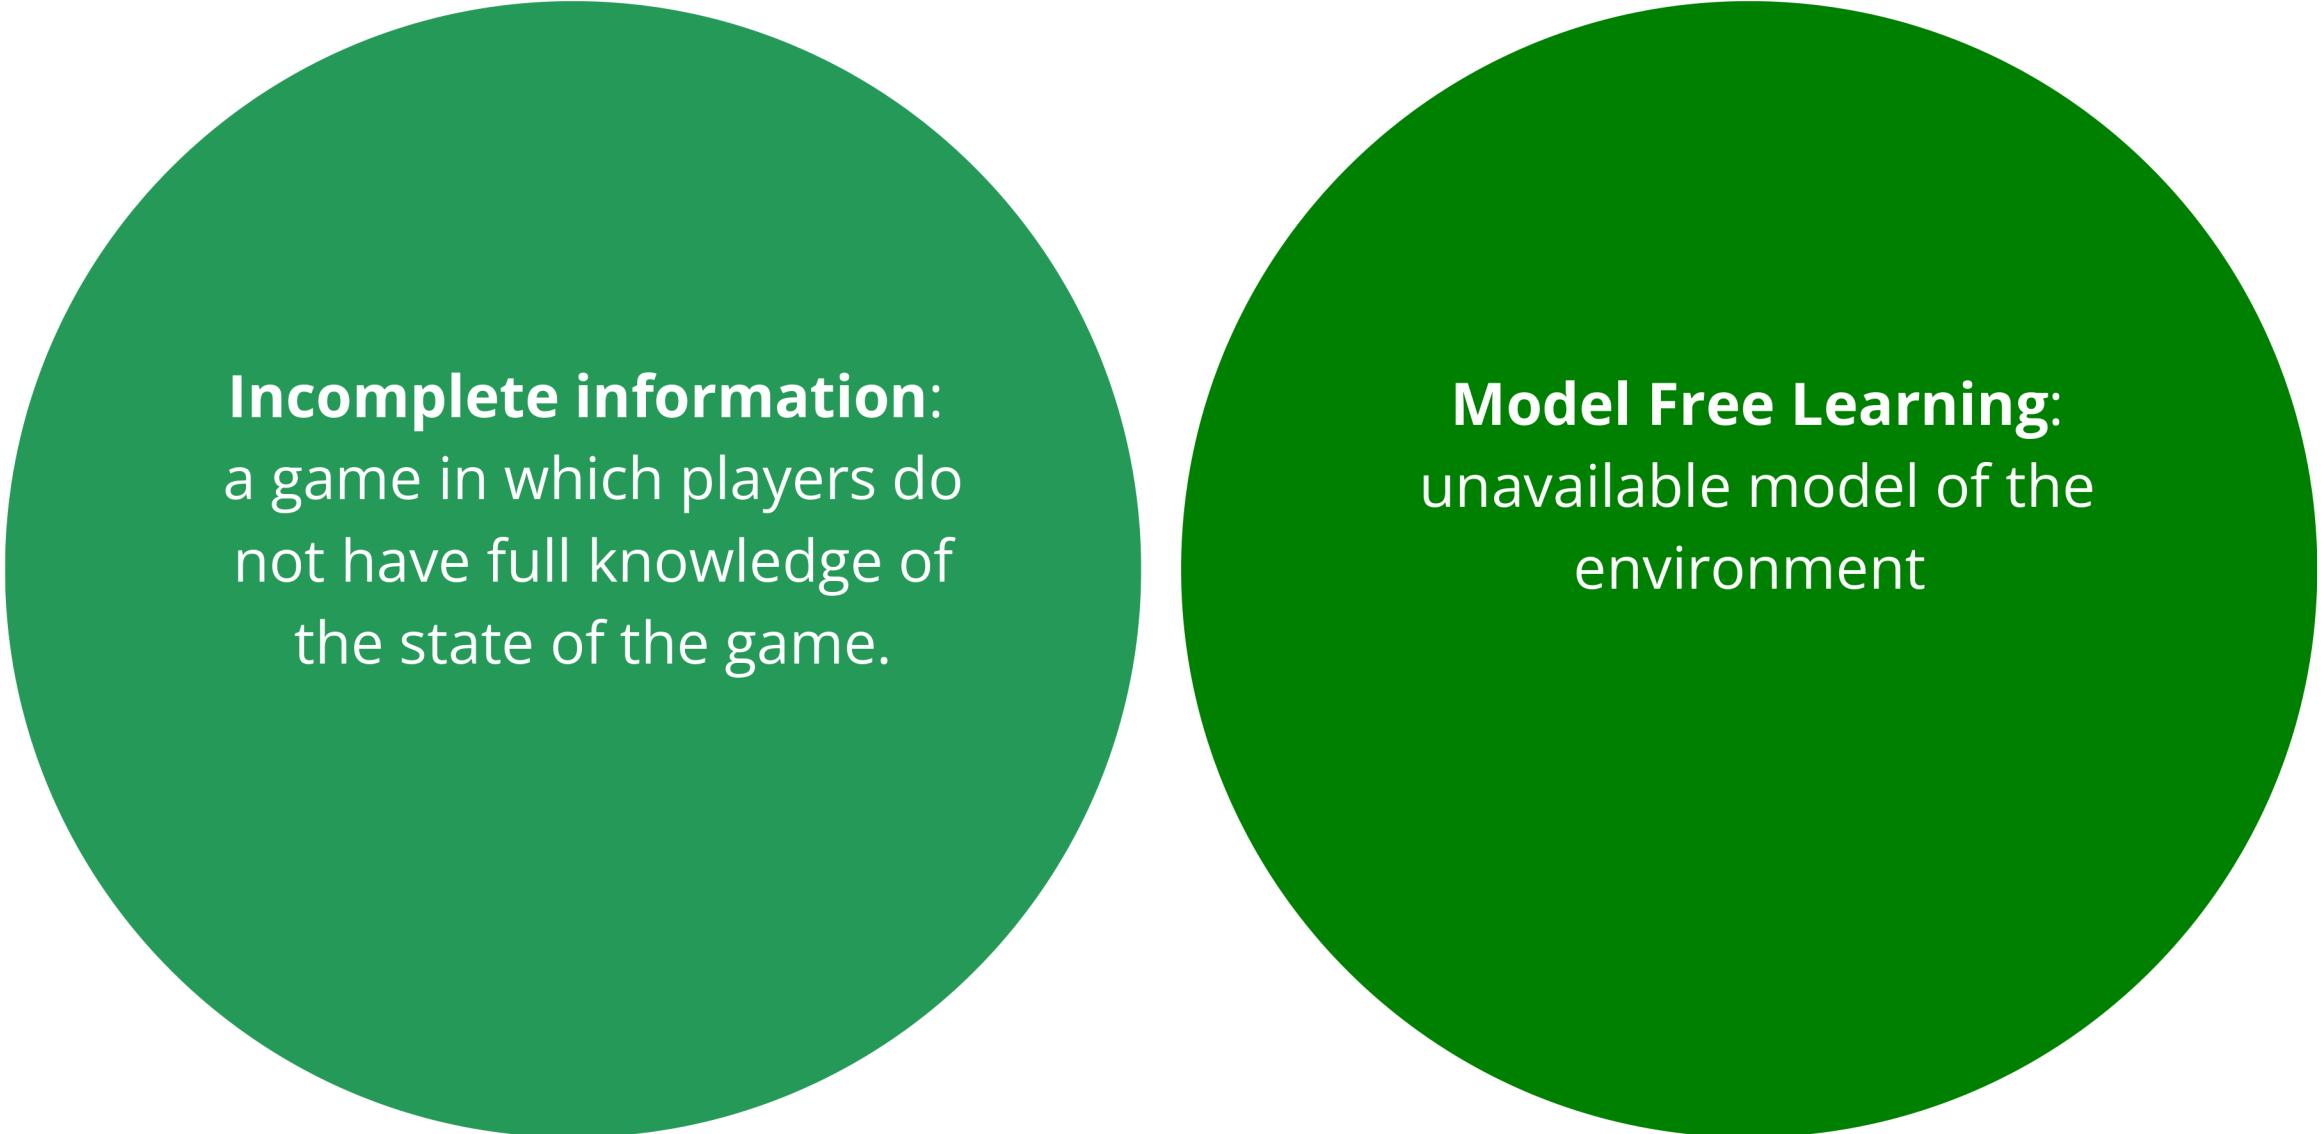

Rewards

Per Round

- Rewards are assigned at the end of each round. The points of the cards on the table are normalized and then they are assigned as follows
 - + Normalized points for the Winner of the Round
 - - Normalized points for the Loser of the Round

Setting

Setting

Incomplete information:
a game in which players do
not have full knowledge of
the state of the game.

Model Free Learning:
unavailable model of the
environment

Setting

Q-Learning

$$Q(s_t, a_t) \leftarrow Q(s_t, a_t) + \alpha(R_{t+1} + \gamma \max_a Q(s_{t+1}, a) - Q(s_t, a_t))$$

$$A_t = \begin{cases} \arg \max_a Q(s_t, a) & \text{with probability } 1 - \epsilon \\ \text{random } a & \text{with probability } \epsilon \end{cases}$$

Setting

Number of states

- It is crucial in RL to determine the number of states for the given problem:

$$\# \text{States} > 40 \cdot \binom{39}{3} \cdot 37 \cdot 2 \sum_{i=1}^{18} i \binom{36}{2i} \approx 10^{17}$$

Deep Q Networks Algorithm

Deep Q Networks

Benefits

- Train RL agents with **large neural networks**
- Learn directly from **high dimensional raw inputs**
- Decrease **unstability** and **divergence** of NN training in RL framework

Deep Q Networks

Experience Replay

- Store the agent's **experience** at each time step in the **replay memory**
- Apply **offline minibatch** updates to **samples** of experience

Data efficiency

Breaks correlations

Smoothing out Learning

Deep Q Networks

Target Network

- Use **separate** net to generate the **targets**
- **Clone** the Q network every **C** updates

Improve stability

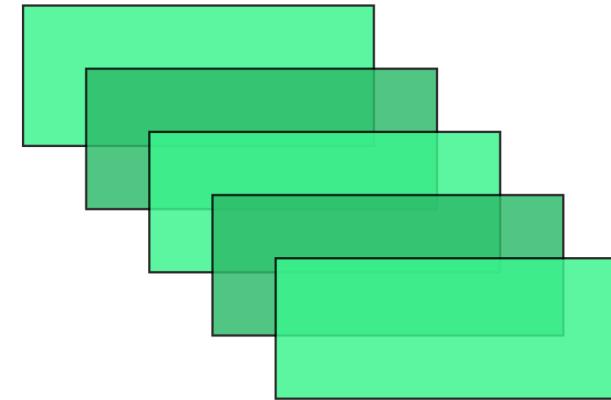

Reduce correlations with targets

Avoid divergence

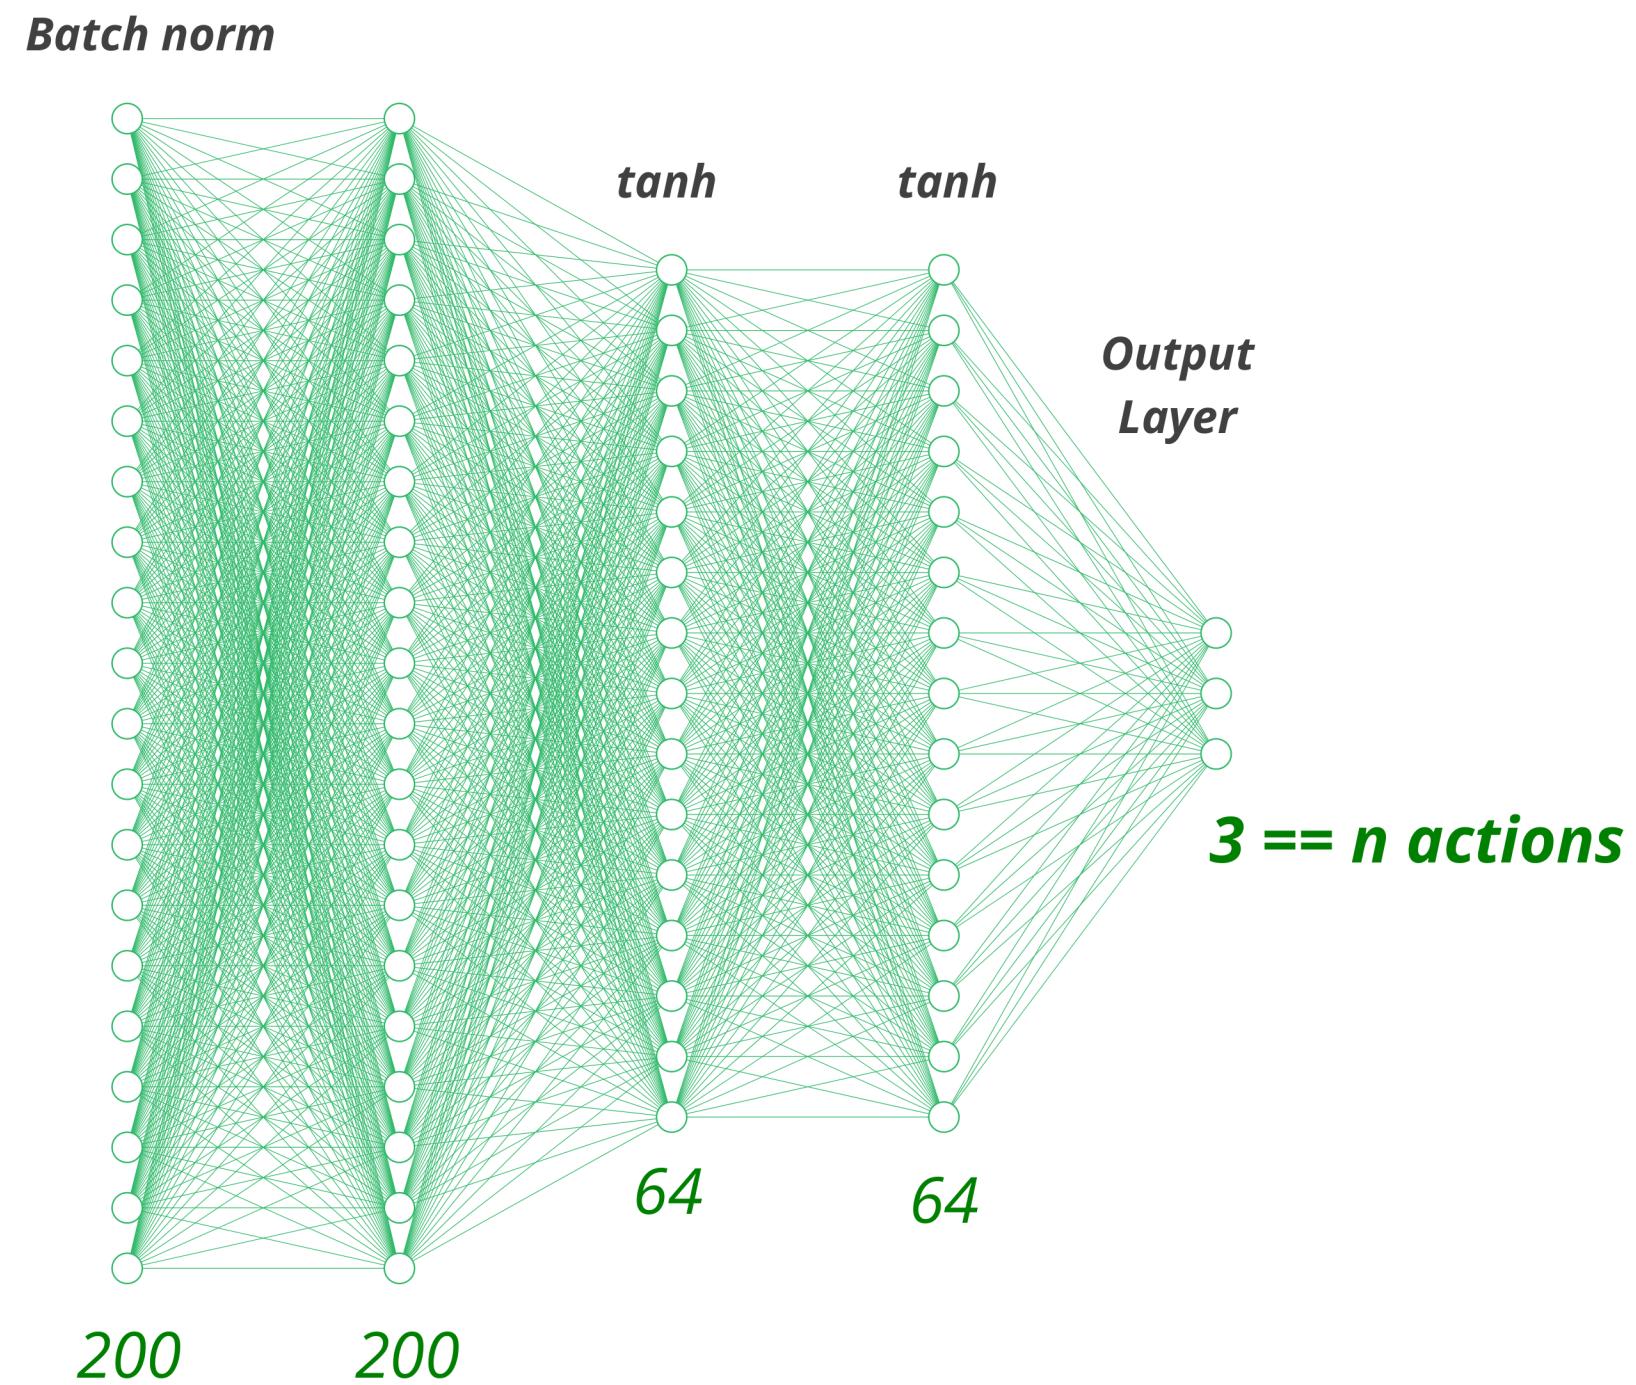

Deep Q Networks

Q Networks Architecture

Input state
 $5 \times 4 \times 10$

Flattening

Deep Q Networks

Pseudocode

- Preprocess function
- Stochastic gradient updates
- Uniform sampling
- Limited memory size

Algorithm 1: deep Q-learning with experience replay.

Initialize replay memory D to capacity N
Initialize action-value function Q with random weights θ
Initialize target action-value function \hat{Q} with weights $\theta^- = \theta$
For episode = 1, M **do**
 Initialize sequence $s_1 = \{x_1\}$ and preprocessed sequence $\phi_1 = \phi(s_1)$
 For $t = 1, T$ **do**
 With probability ε select a random action a_t
 otherwise select $a_t = \operatorname{argmax}_a Q(\phi(s_t), a; \theta)$
 Execute action a_t in emulator and observe reward r_t and image x_{t+1}
 Set $s_{t+1} = s_t, a_t, x_{t+1}$ and preprocess $\phi_{t+1} = \phi(s_{t+1})$
 Store transition $(\phi_t, a_t, r_t, \phi_{t+1})$ in D
 Sample random minibatch of transitions $(\phi_j, a_j, r_j, \phi_{j+1})$ from D
 Set $y_j = \begin{cases} r_j & \text{if episode terminates at step } j+1 \\ r_j + \gamma \max_{a'} \hat{Q}(\phi_{j+1}, a'; \theta^-) & \text{otherwise} \end{cases}$
 Perform a gradient descent step on $(y_j - Q(\phi_j, a_j; \theta))^2$ with respect to the network parameters θ
 Every C steps reset $\hat{Q} = Q$
 End For
End For

Training

Training

Steps*

- 1. Train an **intial model** vs random agent for **500.000 games****
- 2. Learning the **final model** from scratch against the initial model
(**500.000 games**)**
- 3. Evaluation of final trained model:**
 - **500 games versus random and initial agent****
 - **50 games versus human agent****

*Repeated for each version of payoffs

Training

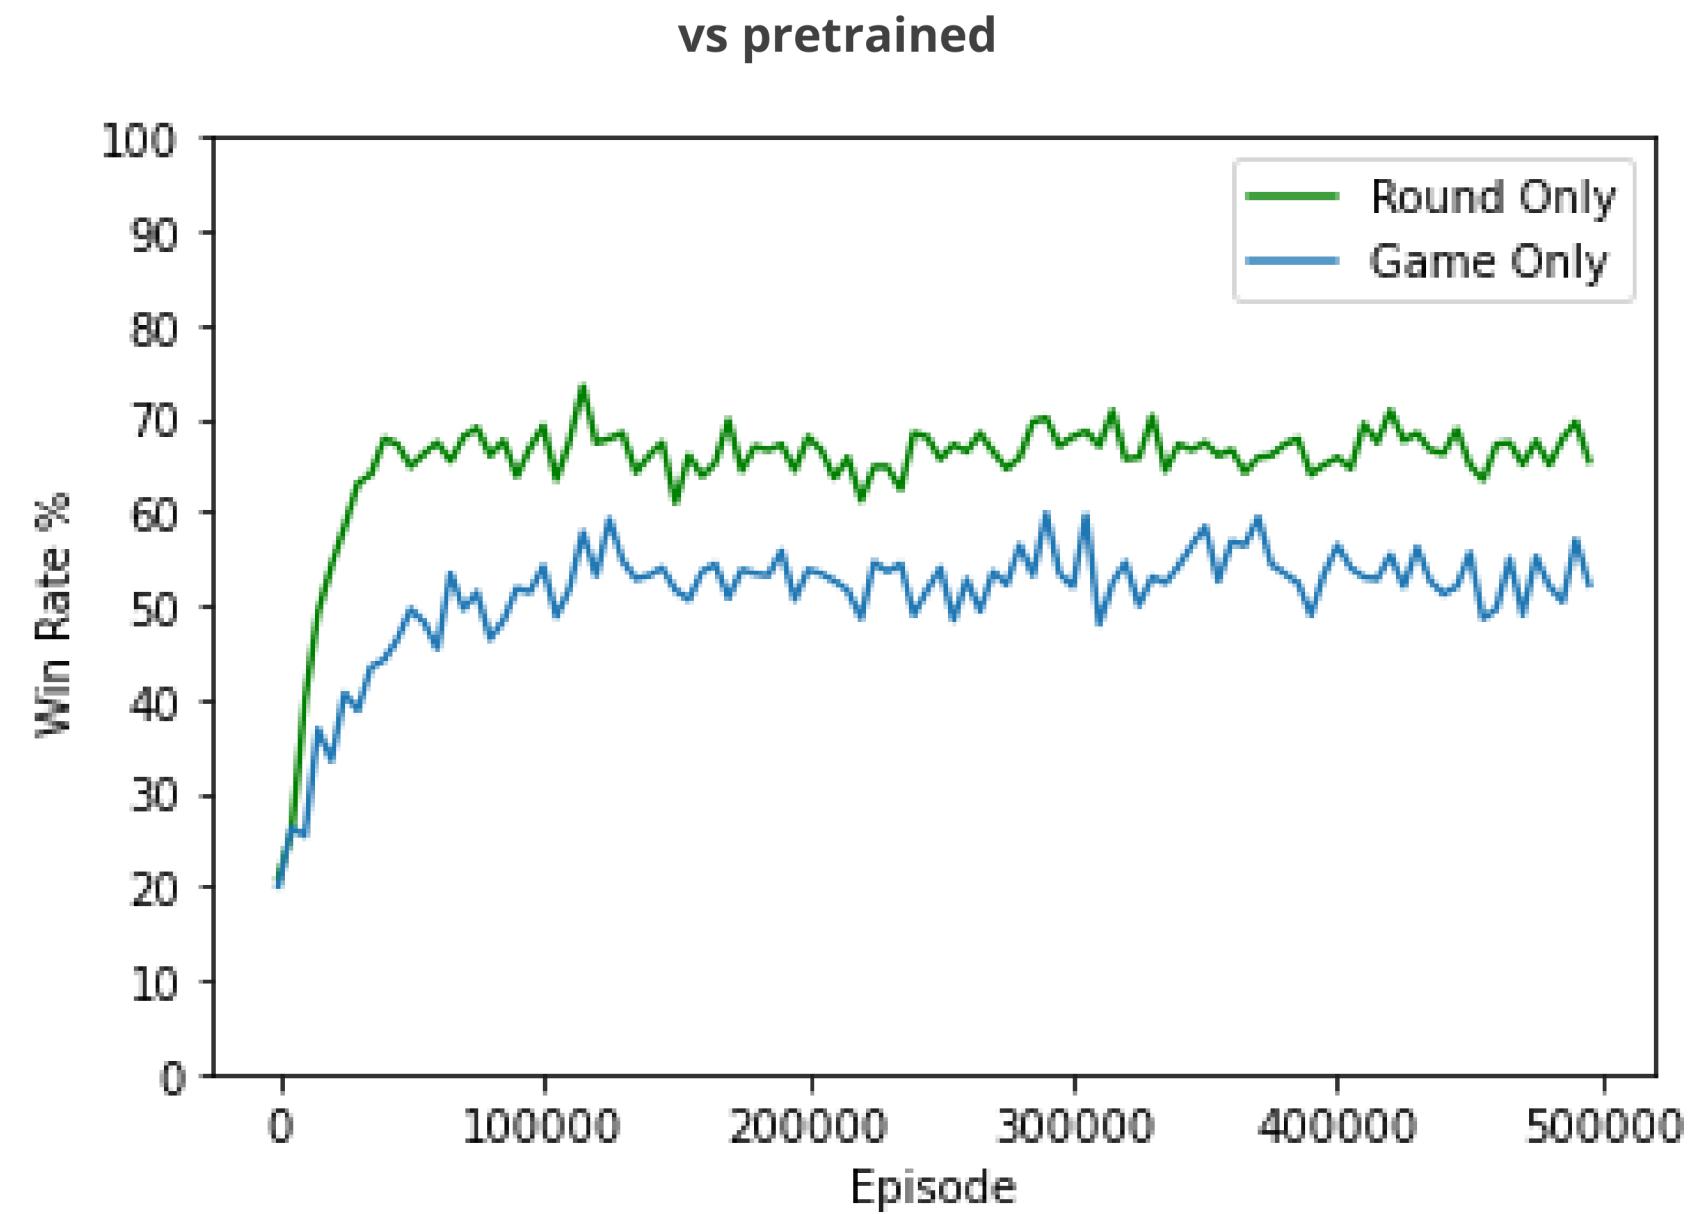

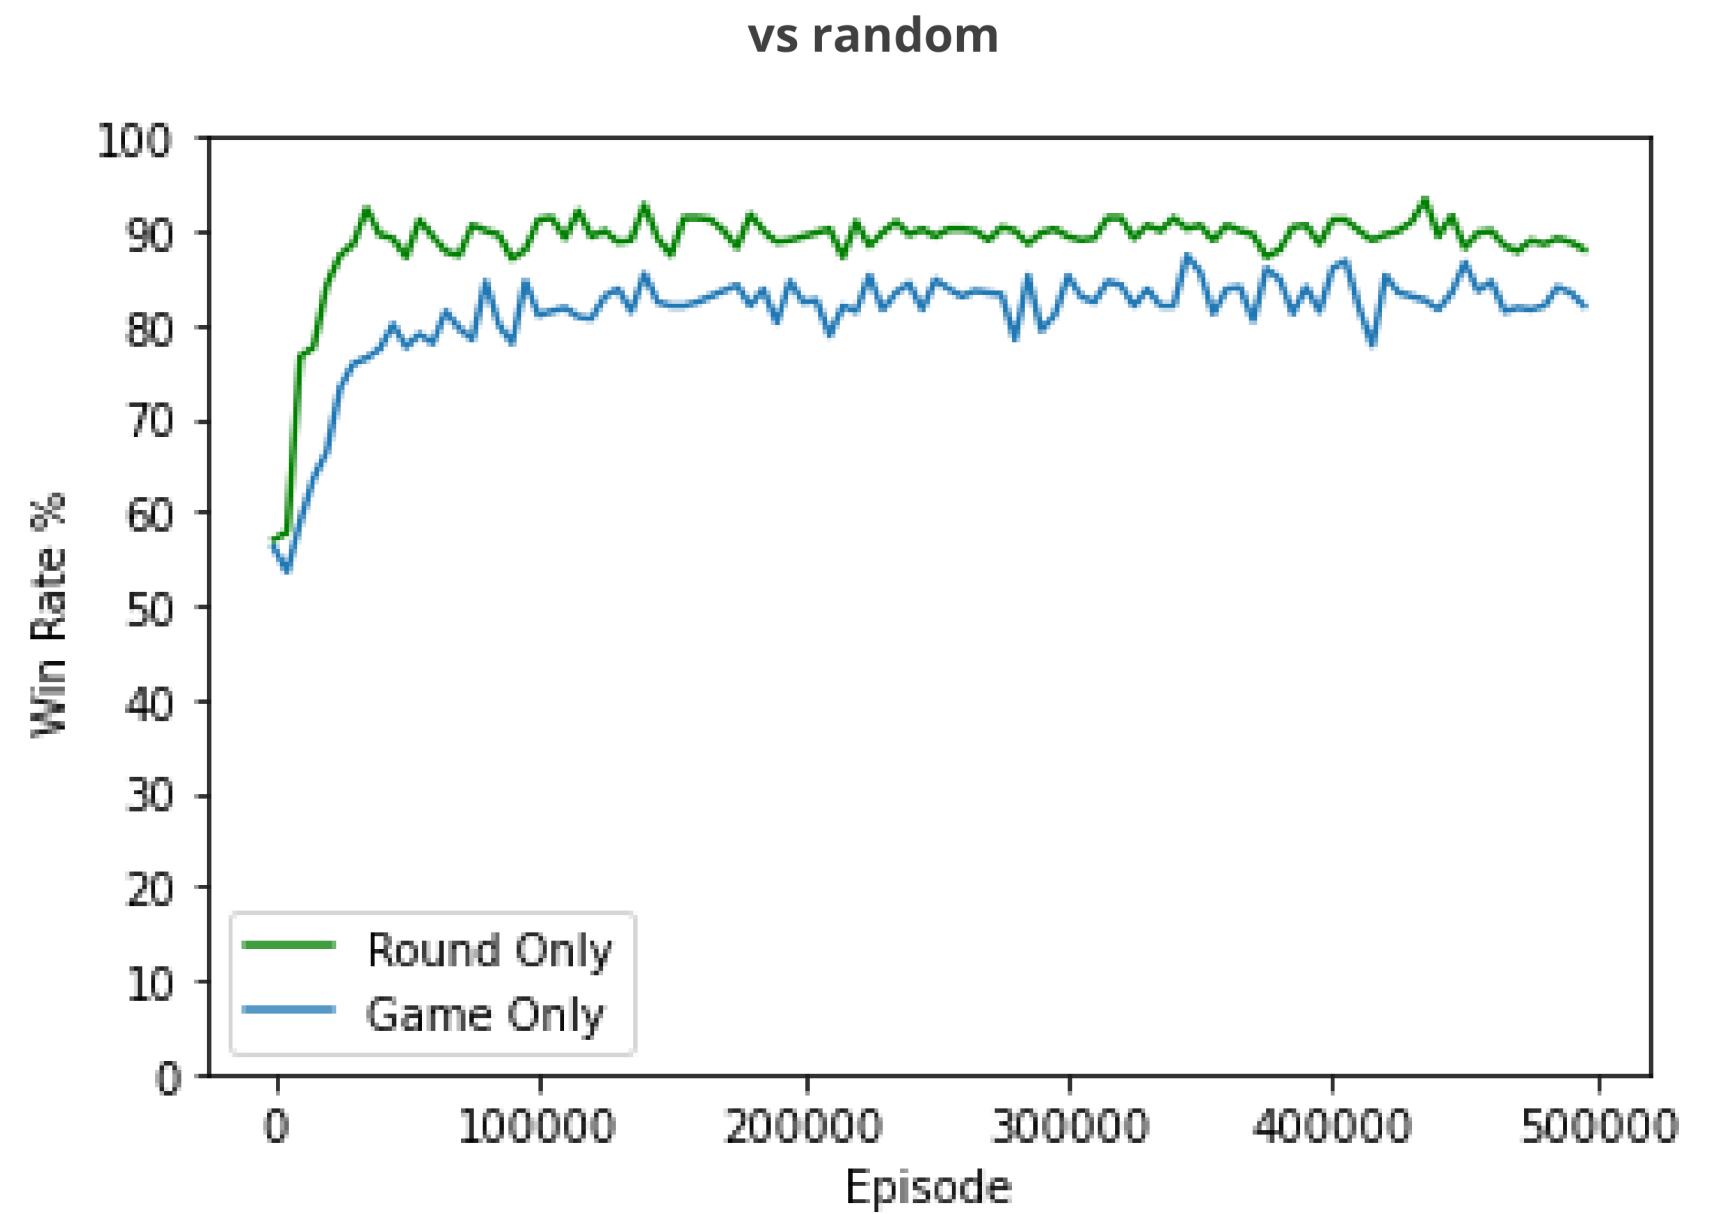

Hyperparameters

- **Replay memory size** = 500000
- **Target network update** = 10000
- **Discount factor** = 1
- **Epsilon start** = 1.0
- **Epsilon end** = 0.1
- **Epsilon decay steps** = 100000
- **Batch size** = 64
- **Learning rate** = 0.00025

Results

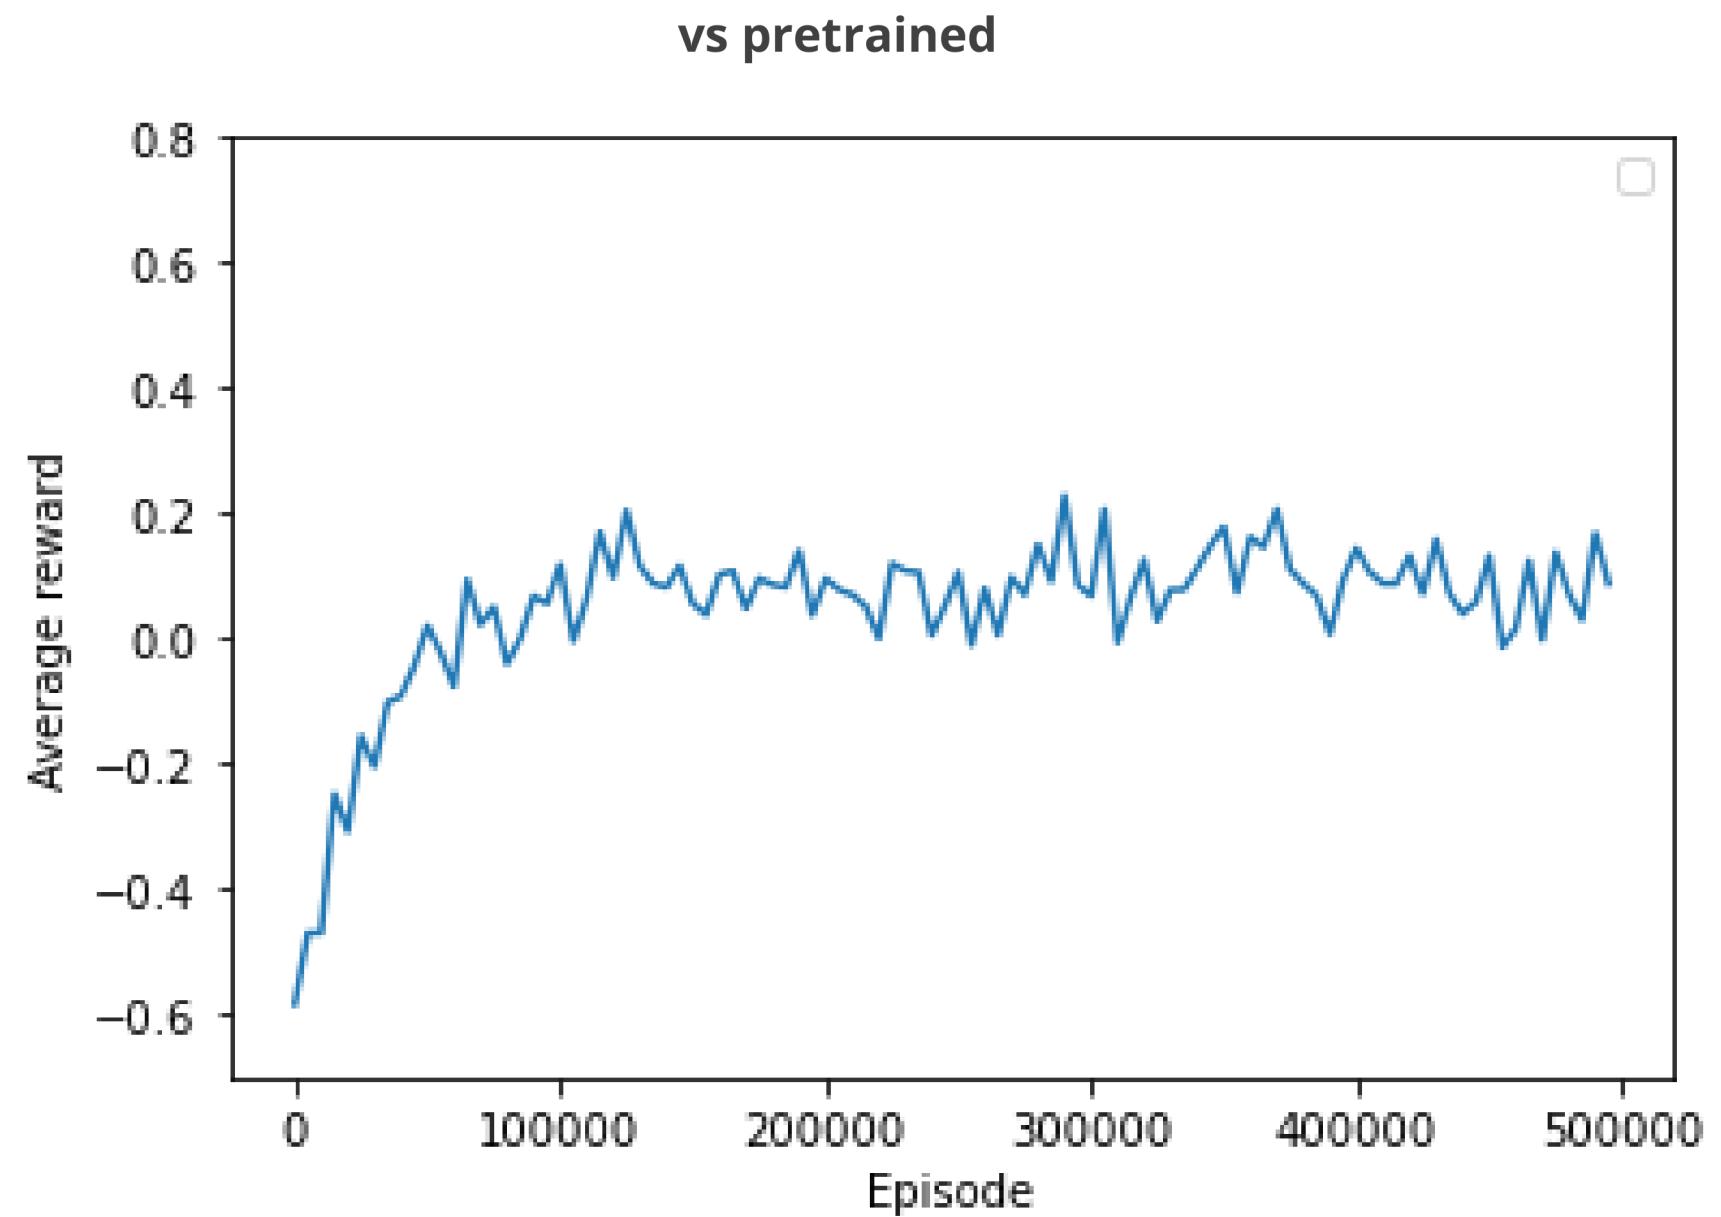

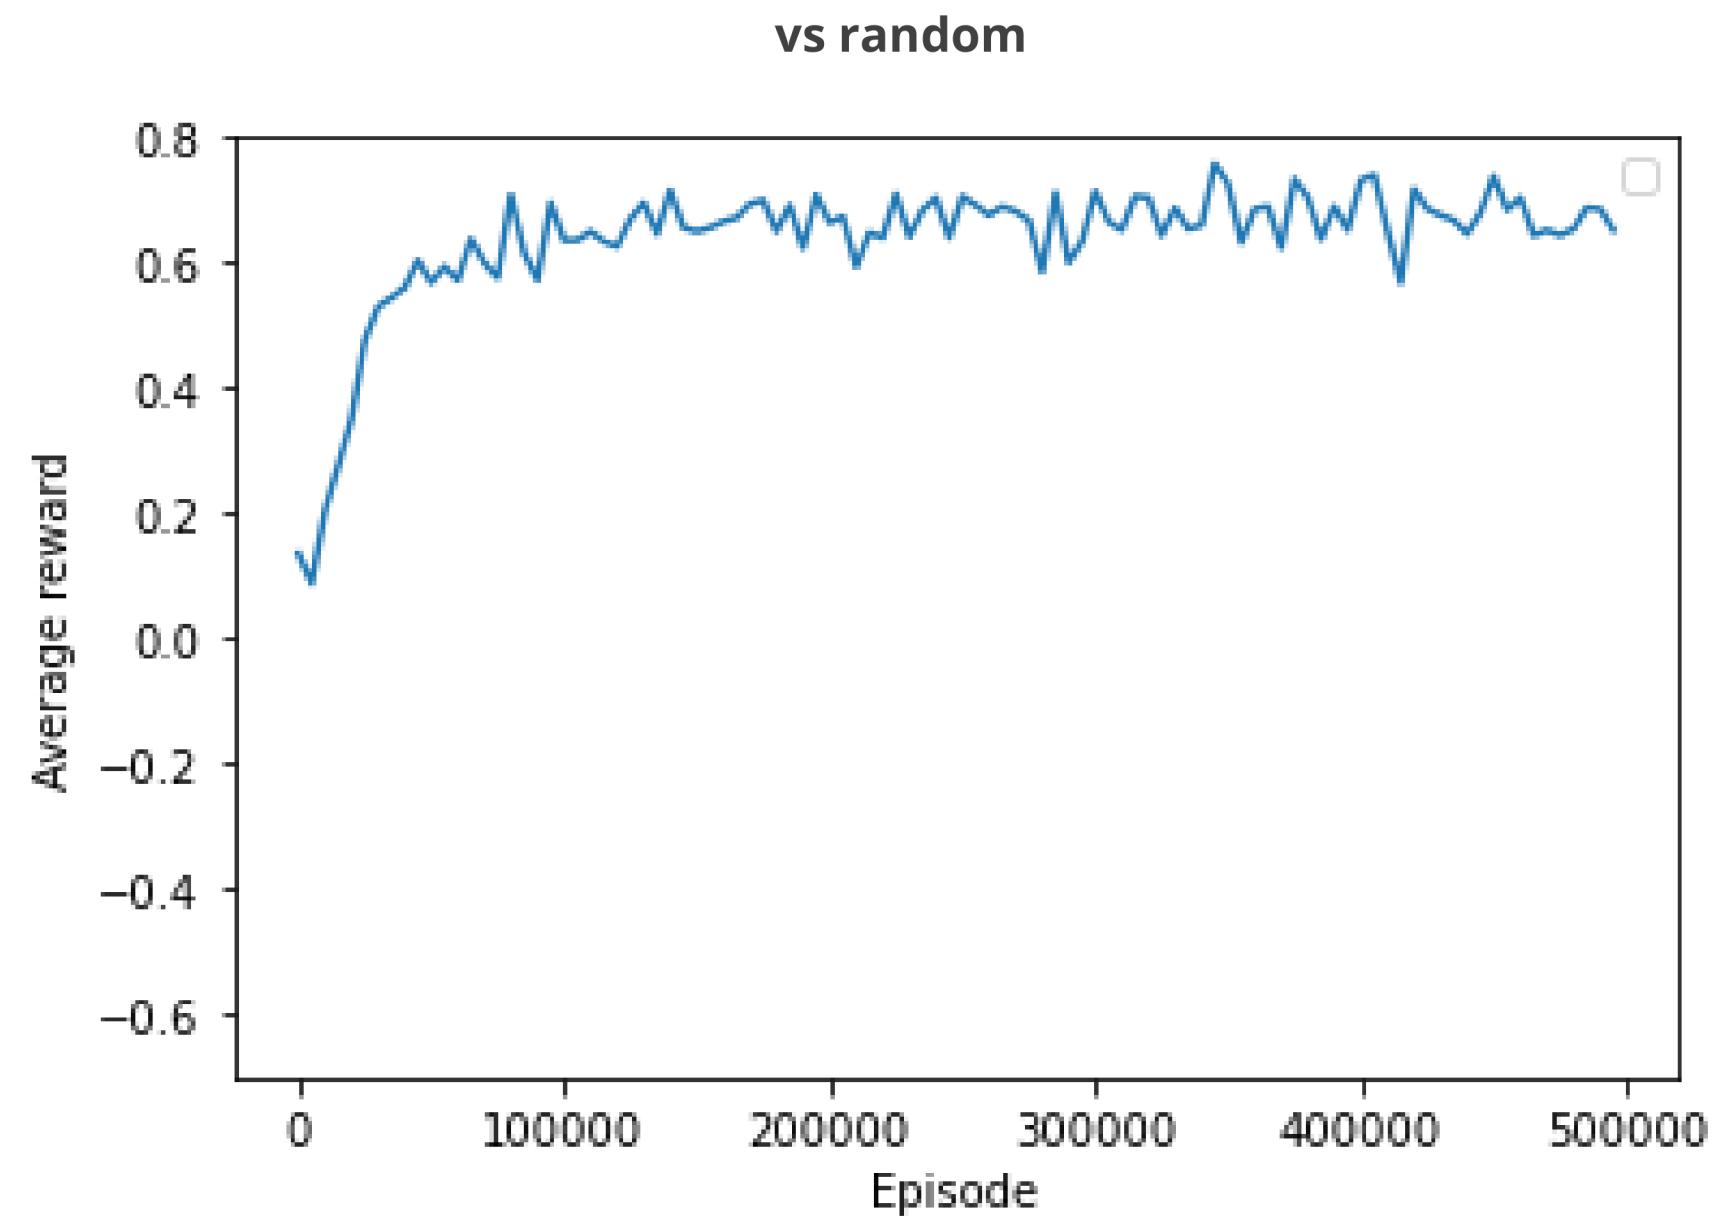

Results

Win Rate

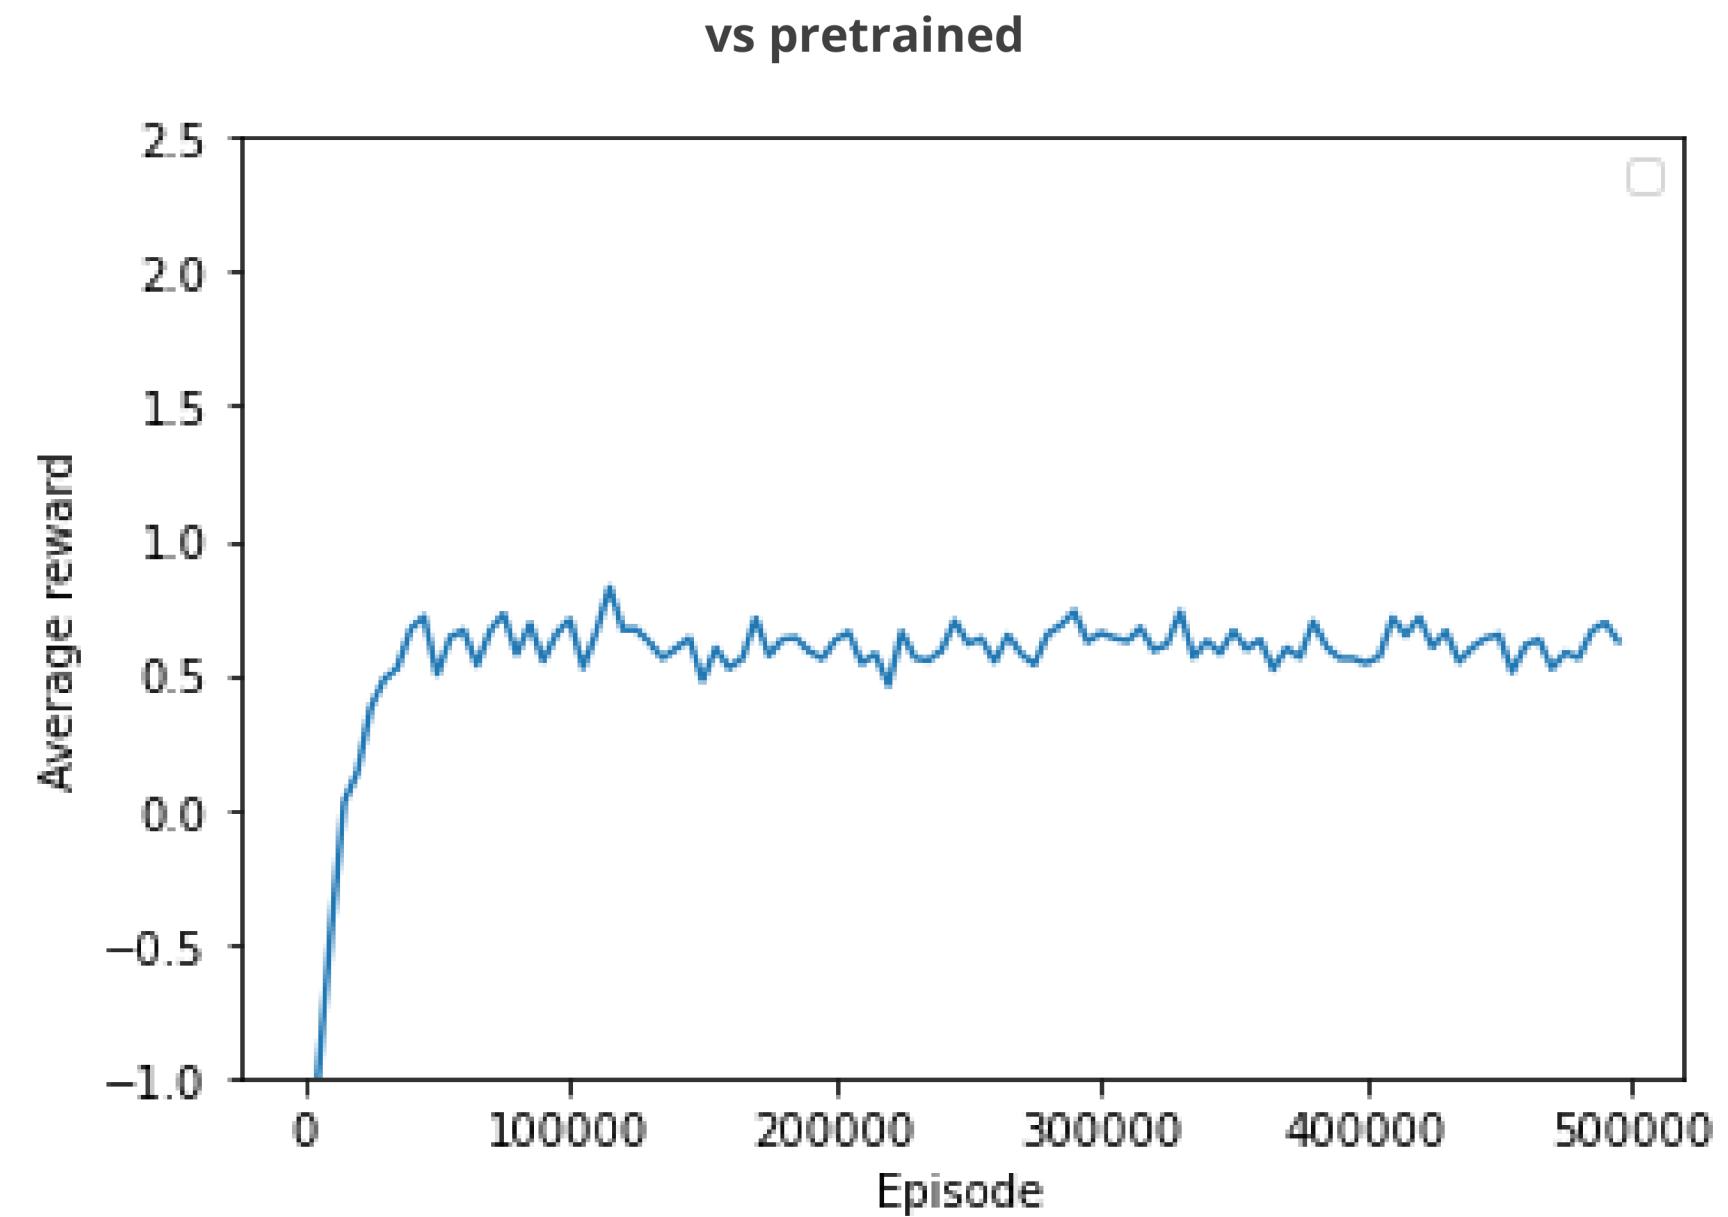

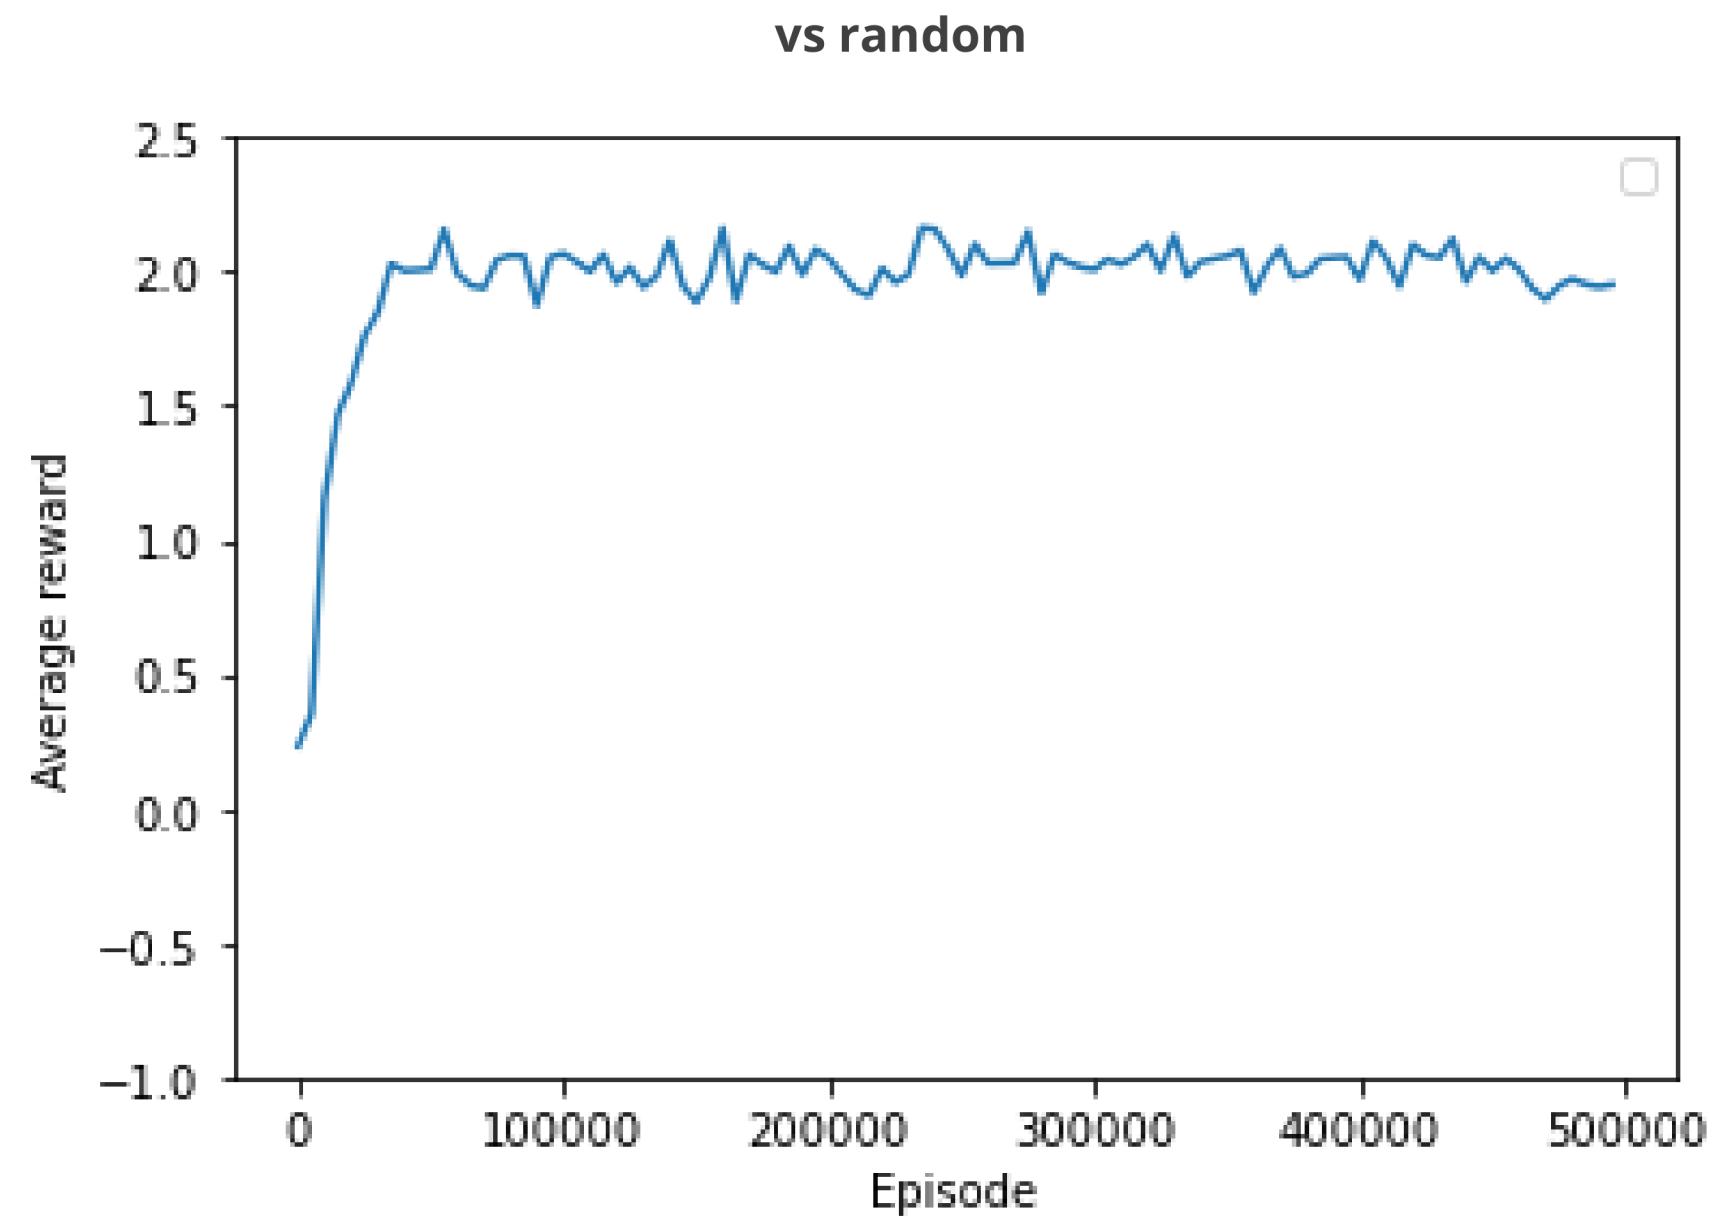

Results

Average game-only reward

Results

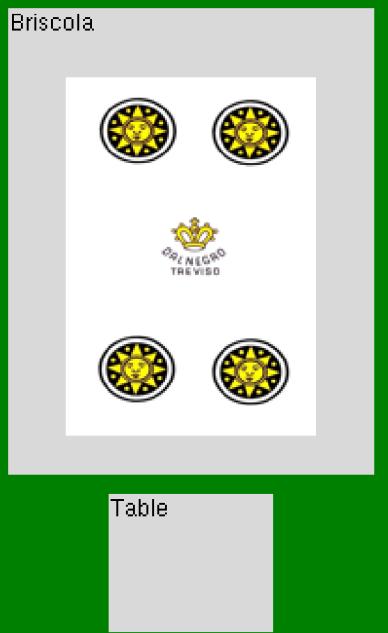

Average round-only reward

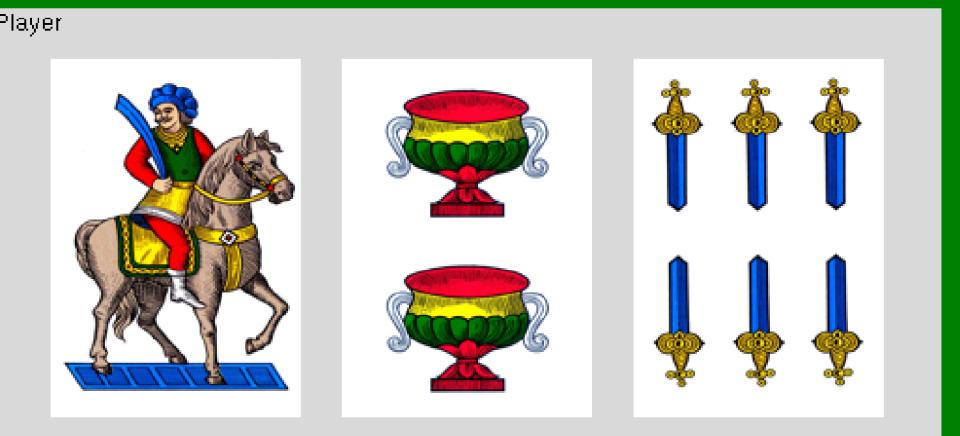

Results

Human Evaluation

- We introduced **Graphical User Interface**, where the opponent is simulated by pre-trained models
- Some tests were performed: **50 games** were played against our best performing agent
- The results showed our **agent winning 37% of games**
